Dynamics of COVID-19 Cases in India: A Statistical Model

Jang Bahadur Prasad^{*1}, Naresh K. Tyagi² and Anushri P. Patil³

Abstract: The COVID-19 cases and related deaths have been increasing throughout the world, without any let up. Health planners, medical professionals, researchers, and scientists have been working relentlessly in containing the disease from the first day, with hardly any success. Hence, study has been under taken with an objective to establish the statistical model of trends in COVID-19 active cases for states of India, so that disease containment performance is assessed objectively, taking model as reference level. The state-wise data from Kaggle website were used to study the case load, cure rate, and levels and trends in active cases by Modified Second Degree Polynomial Model in Indian state using SPSS-22 and Microsoft Office-10. Spot snap of COVID-19situation as on 21st June, 2020 has also been depicted to fill up the gap infirmity. The COVID-19 Active Case Rate varied from 0 to 139 per 100,000 populations.COVID-19 Active Case Rate was highest in Delhi followed by Maharashtra, with best state Meghalaya (COVID-19 with Active case rate = 0.3) and Andaman and Nicobar (2.9). In addition, the model fitted well with Coefficient of Determinants (R^2) as highest (R^2 =0.999), with more than 0.80 R^2 in 23 states, the states with R²less than 0.80 had very less number of COVID-19cases, hence, model did not fit well. The Modified Quadratic Model had the best fit, to assess the performance of states in controlling the COVID-19. The models are expected to be used by Health Planners and Health Professionals, as the models were fitted well in 23 states. Further, the reasons for wide variation in active cases of COVID-19 may be unrest in community due to labour movement. Hence, for containment of COVID-19, the need is to restrict labour movement, and pay attention on enhancement of the health services along with provisioning of public necessities.

Keywords: COVID-19, Inactive Case load, Case Load, States of India, Modified Second Degree Polynomial

Introduction

The outbreak of novel coronavirus disease 2019 (COVID-19) resulted in more than 7,75,000 cases along with 36,000 deaths in more than 160 countries by March 30, 2020 (WHO, 2020; Dong et al., 2020).COVID-19 cases were first detected in Wuhan, China, in December, 2019. Initial outbreak of maximum cases, internationally informed to have history of travel to Wuhan (China) (nCoV-2019 Data Working Group, 2020).Disease COVID-19 spreads from men to men, hence, estimation of fluctuations in transmission over time provide vision in epidemiological aspects of the disease (Camacho et al., 2015). Furthermore, statistical models in COVID-19 spread along with trends in disease will help in understanding outbreak control measures (Riley et al., 2003; Funk et al., 2017).Models and trends in COVID-19 predict possible outbreak of the disease (Cooper et al., 2018), Model may also be help all other nations to control and monitor the disease (Cooper et al., 2006).

Modelling approaches helps in monitoring delays in case-control and case management (Nishiura et al., 2009; Aylward et al., 2014). Additionally, individual data sources might be incomplete, biased, or may only capture certain facts of the outbreak and its dynamics. Appropriate mathematical model captures the average nature, control and management of COVID-19 transmission across countries.

To ease the burden on the healthcare system and providing the best possible care for COVID-19 patients, appropriate models are expected to help in estimation of the risk of infection for better planning, monitoring and control measures. Theoretically, each disease, more so acute and communicable, is expected to follow a pattern, usually, i) Acceleratory phase, ii) Optimum level and ii) De-acceleratory phase. Usually, at the time of evaluation, the time, when data is available, disease is expected to be in de-acceleratory phase. Hence, an attempt has been made to study the levels and trends of the COVID-19 active cases in the states of India. So that necessary action as lockdown, de-lockdown, standardization of line of treatment providing necessities, and enforcement of law are taken at appropriate time, to enhance health and economic benefits of the community.

Materials and Methods

The state-wise data of COVID-19 as on 1st May, 2020weredownloadedfrom website Kaggle (COVID-19 in India, 2020), the platform for extracting the data on novel corona virus diseases 2019, to help better planning and decision. Further, spot snap of COVID-19situation as on 21st June, 2020 has also been depicted to fill up the gap infirmity. Active Cases, in Indian states followed Modified Second-Degree Polynomial as is expected too:

Active Cases =
$$a e^{b_1 t + b_2 t^2}$$

Where, $a = e^{b_0}$

 $b_0, b_1 b_2$ and are the Regression Coefficients.

Active Case Ratio (ACR) per week for estimated Active Cases has been computed as

$$ACR = \frac{EAC_{i+7}}{EAC_i}$$

Where, EAC_{i+7} - Estimated Active Cases at (i+7)th day and EAC_i –Estimated Active Cases at ith day

Seven days Active Case Ratio, at place of one day has been computed to get magnifiable change and to minimising the misreporting. Active Case Ratio is expected to take values greater or equal to zero; '0' indicates no case of COVID-19, '1' peak level of COVID-19, and more than '1' increasing, as Growth Ratio increases. The 95% Confidence Interval (CI) for Active Case Ratio per week has been computed as:

95% CI =
$$e^{\left(log_e(\text{Active Case Ratio}) \pm 1.96\sqrt{\frac{1}{AC_{i+7}} + \frac{1}{AC_i}}\right)}$$

Where, AC_{i+7} - Observed Active Case at $(i+7)^{th}$ time and AC_i – Observed Active Cases at i^{th} time

$$COVID - 19 Rate = \frac{Active Cases}{Population} \times 100,000$$

Case Fatality Rate = $\frac{Deaths}{Cured+Deaths} \times 1,000$

 $\begin{array}{l} \text{Active Case Load} = \frac{\text{Active Cases}}{\text{Cured+Deaths+Active Cases}} \times 100\\ \text{COVID} - 19 \text{ Inactive Case Load} = \frac{\text{Cured+Deaths}}{\text{Cured+Deaths+Active Cases}} \times 100 \end{array}$

Modified Second-Degree Polynomial using Partial Least Square (PLS) Regression Procedure has been used, so that Health Planners, Health Professional can use, the information to assess their performance in containing the disease in comparative perspective. Furthermore, the COVID-19 disease and its fatality rates have been presented as on 21 June, 2020 to cover the gap of unavailability of information. All the available models including Exponential have been tried. The best fit model as per Coefficient of Determination and Visual depiction of observed trends of Active Cases of COVID-19, Modified Second-Degree Polynomial has been selected.

Results

Data of COVID-19 regarding active cases, cured and deaths has been used to depict the disease pattern across the Indian states in the form of statistical models, and the results as per the best Modified Second-Degree Polynomial are presented. Figure 1 reveals COVID-19 Active Cases and Case Fatality Rates by states of India as on 21 June, 2020 indicating that the worst state with highest number of active cases 139 per 100,000 population was Delhi with Case Fatality Rate (63.2 per 1000 Cured and Deaths) followed by Maharashtra with similar figures 51.6 and 85.3 respectively, and the best state was Meghalaya with active cases 0.3 with alarming Case Fatality Rate 29.4 followed by Jharkhand with respective Rates 1.9 and 8.2.

The Modified Quadratic Model for all state of India fitted well with Coefficient of Determinants (R^2 =0.842), with varying trends of states, indicating state-wise patterns (Figure 2).

Table 1 reveals COVID-19 Cases and Deaths by states of India indicating that the best state in controlling the Active Case load of COVID-19 was Andaman and Nicobar (Inactive Case Load =100%) followed by Ladakh (98%), Punjab (91%), and worst was Manipur (Inactive Case Load = 8%), followed by Goa (14%), Maharashtra (30%), Odisha (30%), Chandigarh (30%), Assam (31%) and so on.

Figure 1: COVID-19 Active Cases /100,000 population and CFR by states, India as on June 21, 2020

Source: Estimate was obtained from the data extracted from "#IndiaFightsCorona COVID-19 in India, Corona Virus Tracker | mygov.in." https://www.mygov.in/covid-19 (accessed Jun. 21, 2020).

Table 1: (Continued)

The trends in performance of the states of India in controlling of the COVID-19 has been analysed using Modified Second Degree Polynomial Model, so that unusual in trends of cure of COVID-19 are traced and reasoned out. The model is fitted well for state Maharashtra with Coefficient of Determinant (R^2 = 0.999) followed by states of West Bengal (R^2 =0.995), Uttar Pradesh (R^2 =0.994), Puducherry (R^2 = 0.994), Gujarat (R^2 =0.991), Odisha (R^2 = 0.986), Rajasthan (R^2 =0.980), etc., and worst for the state of Chhattisgarh (R^2 =0.278), Uttarakhand (R^2 =0.372), Ladakh (R^2 =0.416), and Andaman and Nicobar Island (R^2 =0.501).

In Maharashtra, Active Case Ratio from 14 to 21 days was 2.83 with 95% Confidence Interval (CI) 2.12-3.78 and decreased to 1.28 (95% CI: 1.26 - 1.31) by 77 days. Inactive Case Load was increased by around 14% from 14th days to 21st days. After 42 days, it again starts to steadily increased, and was continued by 77 days. Similar pattern was also observed in the state of West Bengal, Uttar Pradesh, Puducherry, Gujarat, Rajasthan, Andhra Pradesh, Telangana, Karnataka and so on with higher Inactive Case Load than Maharashtra. In addition, increased Active Case Ratio was observed in the state of Chhattisgarh, Ladakh, Himachal Pradesh, Assam, Odisha, and Puducherry.

Figure 3a: Average Active Cases ($R^2 = 0.995$) and Active Case Ratio with 95% CI in West Bengal

Figure 3b: Average Active Cases ($R^2 = 0.999$) and Active Case Ratio with 95% CI in Maharashtra

Figure3a, reveals Average Active Cases and Active Case Ratio with 95% CI in West Bengal, indicating that the COVID-19 Active cases increased consistently from 15^{th} days to 65^{th} days. Furthermore, the observed Active Cases were fitted well with Modified Second-Degree Polynomial Model ($R^2 = 0.496$). Fig 3a also indicated that rate of increment in active cases were slow and near to stabilization at 70^{th} days, i.e. the point where Active Cases was same as that of the cases at just previous days. Similarly, the observed Active Cases of Maharashtra state fitted well with Modified Second-Degree Polynomial Model ($R^2 = 0.999$) as shown in fig. 3b. The Active Cases exhibited increasing trend, and the rate of increment in active cases was similar as in West Bengal (Figure3a).

However, Active cases in Andaman and Nicobar Island went down near to X-Axis, indicating of line of stabilization point at nearly 38^{th} days i.e. Active Cases of COVID-19 were almost not there (Fig 3c). In other words, Cases Load decreased fast from 14^{th} day to 20^{th} days and thereafter, increased up to 35^{th} day and then decreased around 50% by 42^{th} days. Thereafter, state achieved 100% Inactive Case Load at 49^{th} days and remained constant till 65^{th} days.

Figure 3c: Average Active Cases ($R^2 = 0.501$) and Active Case Ratio with 95% CI in Andaman and Nicobar

Discussion

The COVID-2019 as a pandemic was declared by WHO on March 11, 2020,killed around 452,669 humans in the word by June 18, 2020 (Coronavirus Update, 18 June, 2020).COVID-19 cases and deaths increased exponentially in the world. Medical professionals, Researchers and Scientists are working hard in controlling the disease from day one. A large number of studies have been published in national and international journals by experts to examine the characteristics of COVID-19 infectious disease (Prasad et al., 2020; Dwivedi et al., 2020; Bhattacharyya et al., 2020).Moreover, there has been history of research on epidemic and pandemic deceases in statistical physics (Pastor et al., 2015; Wang et al., 2016).Furthermore, exponential, quadratic and cubic statistical models have been used to estimate the trends, and to predict the number of cases (Rasad et al., 2020; Dwivedi et al., 2020). However, in the present study Modified Quadratic Model has been used keeping in mind nature of model and disease characteristic.

Modified Quadratic Model for all state together fitted well with Coefficient of Determinant (R^2 =0.842), with similar patterns and with varying degree of states. Whereas, Bhattacharyya (2020) have used four degree polynomial on number of new cases and indicated the similar coefficient of determinants (Bhattacharyya et al., 2020), not much useful to make the necessary action as lockdown, de-lockdown and standardization of line of treatment to enhance health and economic for the benefits of the community, as the shape of the model cyclic and needed to estimate reoccurrence of the disease. According to the present study, the best state in controlling the Case Load of COVID-19 was Andaman and Nicobar (Inactive Case Load=100%) followed by Ladakh, Punjab, etc. and the worst was Manipur (8%), followed by Goa, Maharashtra, Odisha, Chandigarh, Assam and so on.

The levels and trends of performance of the states of India in controlling of the COVID-19 has been analysed using Modified Second Degree Polynomial, so that unusual trends in cure of COVID-19 are traced and reasoned out. For Maharashtra, model is fitted well with $R^2 = 0.999$. Furthermore, Modified Second Degree Polynomial Model is fitted well for the states of West Bengal, Uttar Pradesh, Puducherry, Gujarat, Odisha, Rajasthan, etc. and

worst for the state of Chhattisgarh ($R^2=0.278$) followed by Uttarakhand, Ladakh, and Andaman and Nicobar Island.

In Maharashtra, Active Case Ratio on 21stday was 2.83 as compared to at 14th day, decreased to 1.28 by 77thday. Inactive Case Load was increased steadily from 14thto 77thdays. Inactive Case Load observed higher in the state of West Bengal, Uttar Pradesh, Puducherry, Gujarat, Rajasthan, Andhra Pradesh, Telangana, Karnataka and so on than Maharashtra, but active cases did not reach at declining point. In addition, increasing pattern in Active Case Ratio was observed in the state of Chhattisgarh, Ladakh, Himachal Pradesh, Assam, Odisha, and Puducherry indicating either state have inadequate Health Services or due to movement of labour or due to both. However, Active cases in Andaman and Nicobar Island went down near line of stabilization point at nearly 38th days i.e. Active Case of COVID-19 is almost finished. Andaman and Nicobar state has achieved 100% Inactive Case Load at 49th day and remained constant up to 65th day. Furthermore, fluctuation in Inactive Case Load of Maharashtra, Delhi, etc., cure not be expressed by the model due to movement of labour and density of population.

Conclusion

The COVID-19 Active Case Rate varied from 0 to 139 per 100,000 populations with Delhi as highest followed by Maharashtra. The best state was Meghalaya, and Andaman and Nicobar with respective rates 0.3 and 2.9. The reason for wide variation in active cases of COVID-19 may be unrest in community due to labour movement. Hence, the disease COVID-19 could have been easily controlled by restricting public movement, and providing them necessities. The Modified Quadratic Model has been the best fit and can be used to assess the performance of the states in controlling the COVID-19. The model fitted well with Coefficient of Determinant (R^2)as highest (R^2 =0.999), with more than 0.80 R^2 in 23 states, furthermore, the state with R^2 less than 0.80 had smaller number of cases of COVID-19, hence, model did not fit well.
